A Barvinok–Pataki Theorem for Order Unit Spaces

Adversarial Formalisation Report

Generated via Adversarial Proof Framework (`af`)

Prover–verifier protocol with opus-level adversarial verification

March 1, 2026

Verification Status

This document reports on an *adversarial formalisation* of the Barvinok–Pataki theorem for order unit spaces, carried out using the `af` (Adversarial Proof Framework) CLI tool.

Current state: The proof tree contains 64 nodes. Of these, **15 have been validated** by independent adversarial verifiers, and **49 remain pending** (awaiting verifier acceptance). All 148 challenges raised during verification have been resolved, but the resolved nodes have *not yet been re-verified*. The quality score is 69.4/100.

This is not a finished paper. It is a structured proof skeleton with adversarial annotations. Four genuine mathematical errors were found and corrected during verification (see Section 7). The proof architecture is complete, but full validation requires a second verifier pass.

1 Introduction

This paper establishes an abstract Barvinok–Pataki theorem for state spaces of C^*-algebras and Archimedean order unit spaces, unifying three previously disconnected literatures:

1. **SDP optimisation** — the Barvinok–Pataki rank bounds for extreme points of spectrahedra [3, 6, 7];
2. **Abstract convex geometry** — the Weis–Shirokov face-dimension theorem for constrained convex sets [8];
3. **Operator algebras** — the Alfsen–Shultz face-commutant correspondence for state spaces [1, 2].

The key insight is that the face-commutant correspondence converts the geometric face-dimension bound of Weis–Shirokov into an algebraic bound on the commutant of the GNS representation, yielding a multiplicity bound that simultaneously recovers all known special cases.

2 Main Result

Theorem 2.1 (Barvinok–Pataki for Order Unit Spaces)**.** *Let $\mathcal{A}$ be a C^*-algebra (or, more generally, an Archimedean order unit space), and let $a_1, \ldots, a_m \in \mathcal{A}^{\mathrm{sa}}$ be self-adjoint elements. Define the affinely constrained state space*

$$C = \{\varphi \in S(\mathcal{A}) : \varphi(a_j) = \beta_j,\ j = 1, \ldots, m\}$$

(or with inequality constraints $\varphi(a_j) \leq \beta_j$, or mixed). If φ is an extreme point of C, then:

(I) $\dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) \leq m + 1$, *where $\pi_\varphi(\mathcal{A})'$ is the commutant of the GNS representation.*

(II) Equivalently, if $\pi_\varphi \cong \bigoplus_{j=1}^k \sigma_j^{\oplus n_j}$ is the decomposition into pairwise inequivalent irreducible representations σ_j with multiplicities n_j, then

$$\sum_{j=1}^{k} n_j^2 \leq m + 1.$$

Remark. The theorem extends to $*$-algebras equipped with an Archimedean quadratic module M, in which case $S(\mathcal{A})$ is replaced by the M-positive state space S_M and compactness follows from Tychonoff's theorem rather than Banach–Alaoglu.

3 Proof Architecture

The proof proceeds in three steps, each corresponding to a major node in the proof tree.

3.1 Step 1: Face-Commutant Correspondence (Alfsen–Shultz)

Proposition 3.1 (Node 1.1)**.** *Let $\mathcal{A}$ be a C^*-algebra and $\varphi \in S(\mathcal{A})$ a state with GNS triple $(\pi_\varphi, \mathcal{H}_\varphi, \xi_\varphi)$. The face $F_{S(\mathcal{A})}(\varphi)$ generated by φ in the state space is affinely isomorphic to*

$$D = \{T \in \pi_\varphi(\mathcal{A})'^{+} : \langle T\xi_\varphi, \xi_\varphi\rangle = 1\}$$

via the map $\Phi(T) = \omega_T$ where $\omega_T(a) = \langle \pi_\varphi(a)T\xi_\varphi, \xi_\varphi\rangle$. Consequently,

$$\dim(F_{S(\mathcal{A})}(\varphi)) = \dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) - 1. \tag{1}$$

Proof sketch. The proof establishes five properties of Φ:

(i) **Well-definedness** (Node 1.1.1): ω_T is a state. Positivity uses $T \in \pi_\varphi(\mathcal{A})'$ to commute T past $\pi_\varphi(a)$: $\omega_T(a^*a) = \langle T\pi_\varphi(a)\xi_\varphi, \pi_\varphi(a)\xi_\varphi\rangle \geq 0$.

(ii) **Affinity** (Node 1.1.2): follows from linearity of the inner product (with real convex coefficients).

(iii) **Image in face** (Node 1.1.3): $\omega_T \leq \|T\|\varphi$ as positive functionals, so $\omega_T \in F_{S(\mathcal{A})}(\varphi)$ by the face characterisation ($\psi \in F(\varphi) \Leftrightarrow \psi \leq \lambda\varphi$ for some $\lambda > 0$).

(iv) **Injectivity** (Node 1.1.4): uses cyclicity of ξ_φ and the fact that T commutes with $\pi_\varphi(\mathcal{A})$.

(v) **Surjectivity** (Node 1.1.5): by the Radon–Nikodym theorem for states (Alfsen–Shultz [1], Prop. 5.31).

For the dimension formula (1), D is the cross-section $\pi_\varphi(\mathcal{A})'^+ \cap f^{-1}(1)$ where $f(T) = \langle T\xi_\varphi, \xi_\varphi\rangle$. Since the positive cone spans $\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}$ and has nonempty interior (containing I), the affine span of D equals $f^{-1}(1)$, giving $\dim(D) = \dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) - 1$ (Node 1.1.6). □

3.2 Step 2: Abstract Face-Dimension Bound (Weis–Shirokov)

Proposition 3.2 (Node 1.2)**.** *Let K be a compact convex set in a locally convex space, and let $f_1, \ldots, f_m : K \to \mathbb{R} \cup \{+\infty\}$ be lower semicontinuous generalised affine maps. Define $C = \{x \in K : f_j(x) \leq \beta_j\}$ (or $= \beta_j$, or mixed). For any $x \in C$:*

$$\dim(F_K(x)) \leq \dim(F_C(x)) + m. \tag{2}$$

In particular, if x is an extreme point of C, then $\dim(F_K(x)) \leq m$.

This is taken as an external result: [8], Theorem 2 (single constraint, level sets), Theorem 4 (sublevel sets), and Corollary 5 (multi-constraint induction). The multi-constraint case follows by iterating the single-constraint bound: define $K_0 = K$, $K_j = \{x \in K_{j-1} : f_j(x) \leq \beta_j\}$, and telescope $\dim(F_{K_{j-1}}(x)) \leq \dim(F_{K_j}(x)) + 1$.

Remark 3.3. The naive "constraint propagation" argument — if $y \in F_K(x)$ then $f(y) = \beta$ — does *not* work for sublevel sets, since $f(z)$ can compensate for $f(y) > \beta$ in a convex combination. Weis–Shirokov's proof handles this through a careful face-structure analysis.

3.3 Step 3: Combining the Two Bounds

Proof of Theorem 2.1. The argument proceeds in three lines (Nodes 1.3.1–1.3.4):

1. **Hypothesis verification** (Node 1.3.1): For C^*-algebras, $K = S(\mathcal{A})$ is weak-$*$ compact (Banach–Alaoglu), and $f_j(\psi) = \psi(a_j)$ are continuous affine (by definition of the weak-$*$ topology). The face-commutant correspondence (Proposition 3.1) and the Weis–Shirokov bound (Proposition 3.2) both apply.

2. **Geometric bridge** (Node 1.3.2): By (1), $\dim(F_{S(\mathcal{A})}(\varphi)) = \dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) - 1$.

3. **Extremality bound** (Node 1.3.3): Since φ is extreme in C, $\dim(F_C(\varphi)) = 0$, so by (2), $\dim(F_{S(\mathcal{A})}(\varphi)) \leq m$.

4. **Conclusion** (Node 1.3.4): $\dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) - 1 \leq m$, hence $\dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) \leq m + 1$.

For part (II), by the Artin–Wedderburn theorem (Node 1.4), $\pi_\varphi(\mathcal{A})' \cong \bigoplus_{j=1}^k M_{n_j}(\mathbb{C})$, so $\dim_{\mathbb{R}}(\pi_\varphi(\mathcal{A})'^{\mathrm{sa}}) = \sum_{j=1}^k n_j^2 \leq m + 1$. □

4 Recovery of Classical Results

4.1 Abelian Case: Carathéodory's Theorem

When $\mathcal{A} = C(X)$ for a compact Hausdorff space X, states are probability measures μ on X. All irreducible representations are one-dimensional (point evaluations ev_x), and all multiplicities equal 1 (since the commutant is abelian). For a finitely-supported measure $\mu = \sum_{j=1}^{k} \lambda_j \delta_{x_j}$, the GNS commutant is $\mathbb{C}^k$, giving $\sum n_j^2 = k$.

The main bound yields $k \leq m + 1$: extreme points of the set of probability measures satisfying m moment constraints are discrete measures supported on at most $m + 1$ points. This is the *Richter–Rogosinski theorem*, the measure-theoretic form of Carathéodory's theorem.

4.2 Matrix Algebra: Classical Barvinok–Pataki

When $\mathcal{A} = M_n(\mathbb{C})$, states are density matrices $\rho \in M_n(\mathbb{C})$ with $\rho \geq 0$, $\mathrm{Tr}(\rho) = 1$. The unique irreducible representation is the identity on $\mathbb{C}^n$, so a rank-r state has GNS $\pi \cong \mathrm{id}^{\oplus r}$ with commutant $M_r(\mathbb{C})$. The bound gives $r^2 \leq m + 1$.

The relationship to the standard SDP formulation $r^2 \leq m$ (for the Hermitian PSD cone) is explained by the trace normalisation: the state space $S(M_n(\mathbb{C}))$ already incorporates $\mathrm{Tr}(\rho) = 1$, which in the standard formulation is counted among the m constraints.

Remark 4.1. The full classification by real division algebras (Hurwitz) yields three cases:

(1) *Real:* $\mathcal{A} = M_n(\mathbb{R})$ with transpose involution, $\dim = r(r+1)/2$, bound $r(r+1)/2 \leq m+1$;

(2) *Complex:* $\mathcal{A} = M_n(\mathbb{C})$ with conjugate transpose, $\dim = r^2$, bound $r^2 \leq m + 1$;

(3) *Quaternionic:* $\mathcal{A} = M_n(\mathbb{H})$ with conjugate transpose, $\dim = r(2r - 1)$, bound $r(2r - 1) \leq m + 1$.

4.3 Block-Diagonal Algebras: Mixed Bound

When $\mathcal{A} = \bigoplus_{i=1}^{N} M_{d_i}(\mathbb{C})$, a state $\varphi = \sum_i \lambda_i \mathrm{Tr}(\rho_i \cdot)$ with active blocks $I = \{i : \lambda_i > 0\}$ has GNS $\pi_\varphi \cong \bigoplus_{i \in I} \mathrm{id}_{d_i}^{\oplus r_i}$ where $r_i = \mathrm{rank}(\rho_i)$. The bound becomes

$$\sum_{i \in I} r_i^2 \leq m + 1.$$

This simultaneously constrains ranks within blocks *and* the number of active blocks, interpolating between Carathéodory (all $d_i = 1$) and Barvinok–Pataki ($N = 1$).

Example 4.2. For $\mathcal{A} = M_2(\mathbb{C}) \oplus M_2(\mathbb{C})$ with $m = 4$ constraints: the bound gives $r_1^2 + r_2^2 \leq 5$. This rules out $(r_1, r_2) = (2, 2)$ (which would require $\sum r_i^2 = 8 > 5$). Applying classical BP to each block independently would allow full rank in both blocks. The cross-block constraint is genuinely new.

4.4 Infinite-Dimensional Case: Weis–Shirokov Recovery

When $\mathcal{A} = \mathcal{B}(\mathcal{H})$ for separable $\mathcal{H}$, normal states correspond to density operators ρ with $\mathrm{Tr}(\rho) = 1$. A rank-r state has commutant $M_r(\mathbb{C})$ and the bound gives $r^2 \leq m + 1$, i.e., $r \leq \sqrt{m+1}$. This recovers the Weis–Shirokov bound [8], Theorem 3.

For *unbounded* Hamiltonians H_j (self-adjoint operators affiliated with $\mathcal{B}(\mathcal{H})$), the constraint $f(\rho) = \mathrm{Tr}(H_j \rho)$ defines a lower semicontinuous generalised affine map (as a supremum of continuous affine functions via spectral truncation), and the Weis–Shirokov theorem applies directly via Theorems 2 and 4 of [8].

5 Face Dimension Gap and Automatic Purity

Definition 5.1. The **face dimension spectrum** of $\mathcal{A}$ is $\mathrm{Spec}(\mathcal{A}) = \{\dim(F_{S(\mathcal{A})}(\varphi)) : \varphi \in S(\mathcal{A})\}$. The **face dimension gap** is $G(\mathcal{A}) = \{d \in \mathbb{N}_{>0} : d \notin \mathrm{Spec}(\mathcal{A})\}$.

Theorem 5.2 (Automatic Purity)**.** *If $G(\mathcal{A}) \supseteq \{1, 2, \ldots, \ell - 1\}$ (i.e., the smallest positive face dimension is $\geq \ell$), then for any C defined by $m \leq \ell - 1$ affine constraints, every extreme point of C is a* pure state.

Proof. Let φ be extreme in C. By Theorem 2.1, $\dim(F_{S(\mathcal{A})}(\varphi)) \leq m \leq \ell - 1$. By the gap hypothesis, $\dim(F_{S(\mathcal{A})}(\varphi)) \notin \{1, \ldots, \ell - 1\}$. Since $\dim \geq 0$, the only possibility is $\dim = 0$, i.e., φ is pure. □

Example 5.3. For $\mathcal{B}(\mathcal{H})$: $\mathrm{Spec} = \{0, 3, 8, 15, \ldots\}$ (face dimensions $r^2 - 1$ for $r = 1, 2, 3, \ldots$), so $G \supseteq \{1, 2\}$ and $\ell = 3$. Under $m \leq 2$ energy constraints, all extreme points are pure states. This is the content of Weis–Shirokov Corollary 7.

The face dimension spectrum depends on the algebra type:

Algebra	Spec	**Gap**
$C(X)$, $\lvert X\rvert = \infty$	$\{0, 1, 2, \ldots\}$	$\emptyset$
$M_n(\mathbb{C})$, $n \geq 2$	$\{0, 3, 8, 15, \ldots\}$	$\supseteq \{1, 2\}$
$M_2(\mathbb{C}) \oplus M_2(\mathbb{C})$	$\{0, 1, 3, 4, 7\}$	$\{2, 5, 6\}$
$\mathcal{B}(\mathcal{H})$, $\dim \mathcal{H} = \infty$	$\{0, 3, 8, \ldots\} \cup \{\infty\}$	$\supseteq \{1, 2\}$

6 Applications

6.1 NPA Hierarchy

At finite level k of the NPA hierarchy, the feasible set F_k is an SDP spectrahedron: PSD moment matrices $\Gamma \in M_{N_k}(\mathbb{C})$ with m_k affine constraints. The main theorem (applied with $\mathcal{A} = M_{N_k}(\mathbb{C})$) gives $\mathrm{rank}(\Gamma)^2 \leq m_k + 1$ for extreme points.

Beyond the rank bound, the theorem provides structural information: the GNS decomposition $\sum n_j^2 \leq m_k + 1$ reveals the multiplicity structure of extremal solutions, which classical Barvinok–Pataki does not capture.

Caveat. Interior-point SDP solvers converge to the *analytic centre* of the optimal face, which has *maximal* rank and is typically *not* an extreme point. Post-processing (facial reduction or Burer–Monteiro methods) is needed to obtain low-rank extreme points.

6.2 Quantum Marginal Problem

Let $\mathcal{H} = \bigotimes_{i \in I} \mathcal{H}_i$ be a finite-dimensional multipartite Hilbert space with non-overlapping subsystems $S_1, \ldots, S_k \subseteq I$. The compatible state set is $C = \{\rho \in S(\mathcal{B}(\mathcal{H})) : \mathrm{Tr}_{I \setminus S_j}(\rho) = \rho_j\}$.

Each marginal constraint decomposes into $D_j^2 - 1$ independent scalar affine constraints (where $D_j = \dim(\mathcal{H}_{S_j})$), since the trace component is automatically satisfied by the normalisation $\varphi(1) = 1$. For non-overlapping subsystems, $m = \sum_{j=1}^{k}(D_j^2 - 1)$.

For qubit marginals ($D_j = 2$): $m = 3k$, and the bound is $\sum n_i^2 \leq 3k + 1$.

7 Errors Found During Adversarial Verification

The adversarial verification process discovered four genuine mathematical errors in the original proof draft:

1. **Face dimension spectrum** (Node 1.9.2): The spectrum of $M_2(\mathbb{C}) \oplus M_2(\mathbb{C})$ is $\{0, 1, 3, 4, 7\}$, *not* $\{0, 3, 7\}$ as originally claimed. States supported on two blocks with rank 1 in each create face dimension 1. The gap $\{1, 2\}$ holds only for *simple* algebras ($N = 1$).

2. **"Trivial involution"** (Node 1.6.6): The real PSD cone uses the *transpose* involution $a^* = a^\top$, which is a genuine anti-automorphism, not the identity. The notation $\mathcal{A} = M_n(\mathbb{R})^{\mathrm{sa}}$ was incorrect: the algebra is $M_n(\mathbb{R})$ with transpose involution; the self-adjoint part $M_n(\mathbb{R})^{\mathrm{sa}} = S_n$ is the order unit space, not the algebra.

3. **KMV scope mismatch** (Node 1.10.3): The Klep–Magron–Volčič state polynomial constraints are *nonlinear* in the state φ, but the main theorem handles only *affine* constraints. The application was restricted to the linear sub-case.

4. **Marginal constraint count** (Node 1.10.4): Each marginal contributes $\dim(\mathcal{H}_{S_j})^2 - 1$ constraints, not $\dim(\mathcal{H}_{S_j})^2$. The trace constraint is automatically satisfied by normalisation. For qubits: $m = 3k$, not $4k$.

8 Verification Methodology

The proof was constructed and verified using the `af` (Adversarial Proof Framework) CLI tool, which implements a prover–verifier protocol with strict role isolation.

- **Proof tree:** 64 nodes across 3 levels of depth, with 32 definitions and 14 external references.
- **Verification:** 53 leaf nodes were independently verified by opus-level adversarial agents. 15 nodes were accepted outright; 38 were challenged with 148 total challenges.
- **Challenge resolution:** All 148 challenges have been resolved. Of these, 4 identified genuine mathematical errors (corrected via `af amend`), 6 identified critical logical gaps (filled with additional proof steps), and the remainder were structural metadata issues (missing dependency declarations, incorrect inference types).
- **Re-verification pending:** The 49 amended nodes require a second verifier pass before the proof can be considered fully validated.

Metric	**Value**
Total nodes	64
Validated	15 (23%)
Pending	49 (77%)
Challenges raised	148
Challenges resolved	148 (100%)
Genuine errors found	4
Critical gaps found	6
Quality score	69.4/100

A Proof Tree

The complete proof tree, exported from the `af` framework, is shown below. Each node is annotated with its epistemic state (VALIDATED or PENDING) and the number of challenges raised and resolved.

Proof Tree Legend

- **Node ID**: hierarchical numbering (e.g., 1.3.2)
- **Type**: `claim` (assertion requiring proof)
- **Status**: VALIDATED (accepted by verifier) or PENDING (awaiting verification)
- Challenges shown as [raised/resolved]
